

RAPTOR Flowchart for Finding the Total Number of Characters in a String

Aim: To draw a RAPTOR flowchart that accepts a string as input, calculates the total number of characters using the `Length_Of()` function, and displays the result.

Theory:

A string is a sequence of characters enclosed in double quotes (" "). Strings are immutable, meaning that any modification creates a new string instead of changing the existing one. To store a group of characters, a character array can also be used. RAPTOR provides the **Length_Of()** function to determine the number of characters present in a string. In this experiment, the user enters a string, the program calculates its length, and displays the total number of characters.

RAPTOR Flowchart:

Algorithm:

1. Start the program.
2. Read the input string from the user.

3. Calculate the number of characters using **Length_Of(string)**.
4. Display the total number of characters.
5. End the program.

Sample Input: Computer

Sample Output: Total characters = 8

Result: The RAPTOR flowchart was successfully executed and displayed the total number of characters in the given string using the Length_Of() function.
